Download.Contact matrices Since one of the goals of modeling is to look for patterns, it is useful to create a model that is as complete as possible. When the model is too complex, it will be difficult to find patterns, and the results will likely be useless. However, too simple a model will also prevent the analyst from finding patterns, so it is important to strike a balance. There are several ways to create a model that is too simple. For example, a model can be created so that it is unable to make realistic forecasts. A traditional approach would be to create a model that does not include a demographics portion, and then to try to compensate for it with other variables. You could also forgo the demographics portion of the model and just use the correlations and the indicators that are specific to each product or value chain. The best approach for creating a complex model is to start with a simple model and then include more and more predictors. As more predictors are added, the model will become more sophisticated. Keep in mind that you are always adding new things, so don't worry about adding too much. Most of the time, you will know what variables to include in your model. The problem that you will have to deal with is the choice between adding multiple predictors at once or adding one at a time. Each approach has its pluses and minuses. Adding multiple variables simultaneously When you add multiple predictors at once, you are generally better off than you would be if you were adding one predictor at a time. It is generally best to add one predictor at a time because the number of predictors that you add simultaneously is limited by the fact that your explanatory variables need to be linearly independent. For example, if you are using five predictors, you may be able to add another predictor, but the number of
