1. Field of the Invention The present invention relates to a visual analyzing method and device and, more particularly, to a visual analyzing method and device which can test the conditions of the visual field of the test subject using predetermined visual stimulus patterns to determine the depth of the visual defect of the test subject.

2. Description of the Prior Art Although it has been known that the central visual field of a human is divided into four quadrants by hemiretinae, each hemiretinae has a monocular visual field, and the visual field of each hemiretinae has an area corresponding to one functional eye. Each functional eye has a visual field approximately 160 degrees in horizontal width and approximately 150 degrees in vertical width. The central visual field of a human is viewed by an average person as a portion of a complete circle having a diameter of 160 degrees. It is said that normally each functional eye is capable of realizing a visual field of approximately 80 degrees in horizontal width and approximately 70 degrees in vertical width, and that up to about eight normal eyes are required to cover a visual field of approximately 160 degrees in horizontal width and approximately 150 degrees in vertical width. It is said that visual acuity is lowered as distance from the optical axis is increased and that visual acuity is lowered with the increase of the visual angle in the horizontal direction. It has been known to determine the range of the visual defect of the eye of the test subject by measuring the visual acuity of the test subject in three directions, i.e., right, left
